CHAPTER 8

DIGITAL DATA BUS ACQUISITION FORMATTING STANDARD

8.1 General

This standard describes output data formats for the acquisition of all the traffic flowing on various digital data buses. The formats permit the capture of data from multiple data buses within a single system. Other constraints such as Radio Frequency (RF) bandwidth and tape recording time will dictate the actual number of buses processed by a single system. Standards for both composite telemetry Pulse Code Modulation (PCM) and tape recorder PCM formats are presented.

Although specifically designed to satisfy the requirements of 100 percent MIL-STD-1553 bus and Aeronautical Radio Incorporated (ARINC) 429 channel acquisition, the formatting provisions of this standard may be used in other applications when the data source and content are similar enough to permit easy adaptation. Users should contact the appropriate range to ensure any adaptations are compatible with that range.

In addition to the total data capture technique and format presented in this chapter; “Selected Measurement” methods are available to acquire less than 100 percent of bus data. Selected Measurement methods result in PCM formats conforming to Chapter 4 of this standard and fall outside the scope of this chapter.

This chapter presents the general requirements for data formatting followed by individual sections addressing specifics pertaining to MIL-STD-1553 and ARINC 429 respectively.

8.2 Word Structure

The following subparagraphs describe the general word structure to be used for the formatted output. Specific word structures and definitions are provided as part of each bus/channel subsection.

8.2.1 Field Definition. The formatted data shall be a 24-bit word constructed as shown in Figure [8-1, part \(a\)](#).

8.2.2 Most Significant Bit. The most significant bit (bit 1) of each formatted word may optionally be an odd parity bit generated for the resulting formatted word or an additional bit appended to the Bus/Group Identification Label as described in paragraph 8.2.3.

8.2.3 Bus/Group Identification Label. Each word shall also carry a Bus or Group Identification Label as shown in Figure [8-1, part \(b\)](#). For this application, a bus refers to a MIL-STD-1553 bus (or dual redundant bus pair) and a group refers to a collection of up to four ARINC 429 channels. The Bus/Group Identification Label may optionally be three or four bits in length dependent on the exercise of the option to use or not use a parity bit. If not used, the parity bit,

or bit one (1), is appended to the Bus/Group Identification Label to increase the bus count from a maximum of eight (3 bits) to a maximum of 16 (4 bits).

8.2.4 Content Identification Label. Each incoming bus word, auxiliary/user input, or time word shall be appropriately labeled with a 4-bit Content Identification Label (see Figure 8-1 part (c)). Content Identification Labels are specific to each bus type and are detailed in later sections.

8.2.5 Information Content Field. Data extracted from the data bus shall maintain bit order integrity and be inserted into the Information Content field as specified for each bus type. Transposing or reordering of the bits is not permitted.

BIT POSITION

c. Content Identification Label Definition; Bits 5, 6, 7, & 8																							

Figure 8-1. Word construction.

8.2.6 Fill Words. Fill words, required to maintain continuous PCM output, shall have the following sequence as the Information Content pattern:

1010 1010 1010 1010 (AAAA hexadecimal)

8.2.7 Content Identification Label. The Content Identification Label indicating buffer overflow (0000) and appropriate Bus/Group Identification Label tag shall be appended to the first word placed into the buffer after the buffer becomes available for data storage. This word should be an "extra" word, not the next available piece of data. Bits nine (9) through 24 are available for system level diagnostics and are not specified here. Tagging in this manner marks the point of data discontinuity and preserves the integrity of the next piece of data.

8.2.8 Cyclic Redundancy Check (CRC). CRC is a very powerful technique for obtaining data quality. An optional CRC word may be appended as the last positional word of each PCM frame (see Figure 8-2). The CRC word shall be composed of Parity and/or Bus/Group Identification Label, Content Identification Label, and 16 bits of a Frame Check Sequence (FCS). The FCS shall fill the Information Content field (bits 9 – 24). The following CRC-16 polynomial shall be used to generate the FCS. None of the 24 bits making up the entire CRC word shall be used in the calculation of the 16-bit FCS.

CRC-16 polynomial: $X^{16} + X^{15} + X^2 + 1$

 <p>NOTE</p>	<p>Exercise care when assigning bus identification and content identification label codes to the CRC word. Although a positional word in the frame, legacy-processing algorithms may falsely identify the information if one of the bus data labels (1111 – 1000) is used as the content identification label.</p>
--------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

8.3 Time Words

The following describes the structure and use of time words within the formatted output.

The time words dedicated to providing timing information are defined Chapter 4 of this standard. These time words are designated as high order time, low order time, and microsecond time. The MIL-STD-1553 bus data acquisition applications use an optional fourth time word, designated as response time. The response time word has the same structure as the microsecond time word. Time word structure shall follow the 16-bit per word format shown in Chapter 4, Figure 4-3, and be placed into the Information Content field (bits nine (9) through 24) in bit order.

8.4 Composite Output

8.4.1 Characteristics of a Singular Composite Output Signal. The following subparagraphs describe the characteristics for a singular composite output signal.

- a. The composite, continuous output shall conform to the requirements for Class 2 pulse-code modulation as stated in Chapter 4 of this standard.
- b. The data shall be transmitted most significant bit (bit 1) first.
- c. The bit rate is dependent on several factors including bus loading and auxiliary inputs and shall be set to a fixed rate sufficient to preclude any loss of data.
- d. The order of bus words must remain unaltered except in the case of a buffer overflow.
- e. The frame length shall be fixed using fill words as required and shall be ≥ 128 words and ≤ 512 words including the frame synchronization word.
- f. The frame synchronization word shall be fixed and 24 consecutive bits in length. The pattern, also shown in Appendix C, table C-1, appendix C, is:

1111 1010 1111 0011 0010 0000 (FAF320 hexadecimal).

- g. A frame structure employing frame time is recommended but optional. If frame time is used, the frame structure shall consist of the frame synchronization word, followed by the high order time word, followed by the low order time word, followed by the microsecond time word, followed by the data words from all sources making up the composite signal up to the frame length specified in subparagraph [8.4.1e](#) above (also see Figure [8-2](#)). If frame time is not used, the frame synchronization word shall be followed immediately by the data words. If a Cyclic Redundancy Check word is not used, the last word in the frame is data word N.
- h. The following describes the recommended techniques for recording the composite output signal.
 - 1) Longitudinal recording shall conform to the PCM recording provisions Appendix D of this standard.
 - 2) Recording using parallel HDDR or rotary head recorders offers the advantage of inputting a single high bit rate signal to the recording system. The input PCM signal shall conform to the appropriate sections of this standard.
 - 3) If recording using digital recorders or other noncontinuous recording processes with buffered inputs, the fill words, inserted to provide a continuous output stream, may be eliminated.

	<p>Additional care must be exercised in data processing and reduction if the last word in a composite stream is a MIL-STD-1553 command word. The associated message time tag will not appear until <u>after</u> the synchronization and time words in the next frame.</p>
-----------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

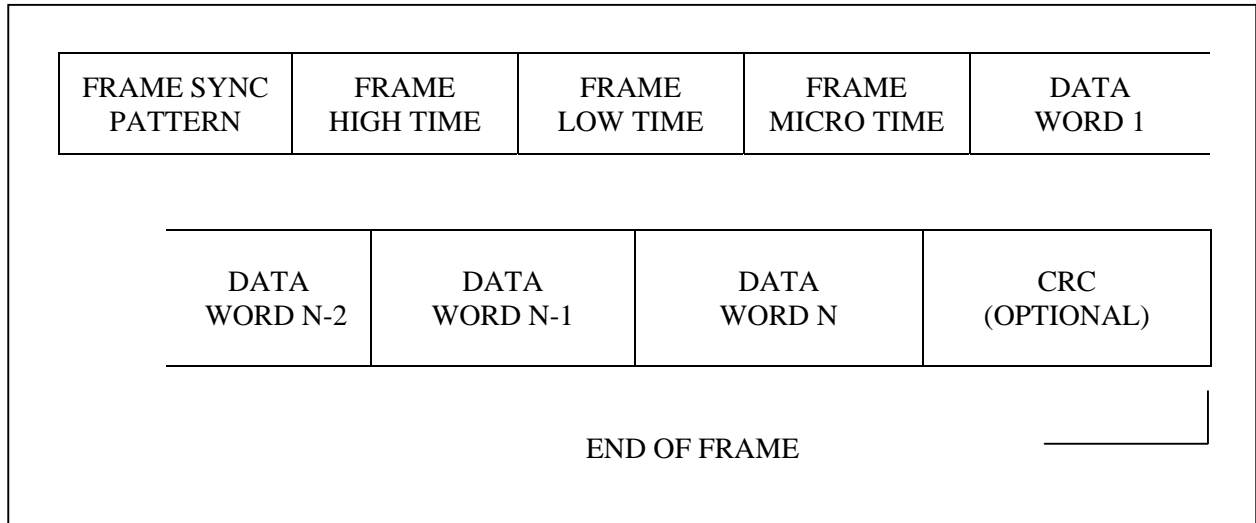

Figure 8-2. Composite frame structure.

8.5 Single Bus Track Spread Recording Format

8.5.1 Single Bus Recording Technique Characteristics. The following subparagraphs describe the characteristics of a single bus recording technique using a multiple tape track spread output format.

- a. The target tape recorder/reproducer for a track spread format is a longitudinal fixed-head machine described in Appendix D of this standard and not one employing parallel high density digital recording (HDDR) or rotary head recording characteristics.
- b. The code generated for longitudinal tape recording shall be RNRZ-L or Bi ϕ -L as described in Chapter 4 and Appendix D of this standard.

	<p>Bit rates less than 200 000 bits per second are not recommended when using RNRZ-L.</p>
-------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------

- c. To extend recording time while still acquiring 100 percent of bus data, a multiple track spread recording technique is presented as follows:
- 1) When necessary to use more than one tape recording track (to extend record time), separate PCM streams shall be created and delayed by $24/TK$ bits with respect to each other, where TK represents the number of tape tracks used for a given bus.
 - 2) When multiple track-spread recording is required, the track spread shall be on a bus basis such as bus number 1 spread over four tracks, and bus number 2 spread over two tracks. The maximum number of tracks per bus shall be limited to four.

 <p>NOTE</p>	Consideration should be given to spread track assignment. All tracks associated with a given bus should be recorded on the same head stack.
------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------

- 3) Each stream shall have a frame synchronization pattern 24 bits in length, conforming to subparagraph [8.4.1f](#).
- 4) The word structure shall be identical to that described in paragraph [8.2](#).
- 5) The frame length shall be fixed and shall be the same for each track used for a given bus. The frame length shall conform to the requirements of paragraph [8.4.1e](#).
- 6) The data shall be formatted such that it is transmitted (recorded) most significant bit (bit 1) first.
- 7) The use of a Cyclic Redundancy Check word as described in paragraph [8.2.8](#) is optional. If used in the track spread application, a CRC word must be generated and appended to each of the PCM frames for that bus.

8) A structure employing frame time is recommended but optional. The following describes a four-track spread example using frame time.

- TK1. The PCM stream designated TK1 shall be constructed as the frame synchronization word, followed by the high order frame time word, followed by data words (see Figure 8-3).
- TK2. The PCM stream designated TK2 shall be constructed as the frame synchronization word, followed by the low order frame time word, followed by data words.
- TK3. The PCM stream designated TK3 shall be constructed as the frame synchronization word, followed by the microsecond frame time word, followed by data words.
- TK4. The PCM stream designated TK4 shall be constructed as the frame synchronization word, followed by the first data word, followed by other data words.

Note: Schemes using one, two, or three tracks for a given bus shall follow like construction; that is, sequencing through the data track by track. If frame time is not used, data words shall immediately follow the frame synchronization patterns.

 <p>NOTE</p>	<p>Additional care must be exercised in data processing and reduction if the last word in the final track spread stream is a MIL-STD-1553 command word. The associated message time tag will not appear until <u>after</u> the synchronization and time words in the next frame.</p>
--------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Figure 8-3. Multiple tape track spread format (4-track spread example).

8.6 MIL-STD-1553

The following subparagraphs describe specific formatting requirements for the 100 percent acquisition of MIL-STD-1553 bus information.

8.6.1 Definitions.

- a. Bus Monitor. The terminal assigned the task of receiving bus traffic and extracting all information to be used at a later time.
- b. Data Bus. All hardware including twisted shielded pair cables, isolation resistors, and transformers required to provide a single data path between the bus controller and all associated remote terminals.
- c. Dual Redundant Data Bus. The use of two data buses to provide multiple paths between the subsystems.
- d. Bus Loading. The percentage of time the data bus is active.
- e. Maximum Burst Length. The maximum length of a continuous burst of messages with minimum length message gaps.
- f. Bus Error. A condition that violates the definition of MIL-STD-1553 word structure. Conditions such as synchronization, Manchester, parity, noncontiguous data word, and bit count/word errors are all considered word type errors. System protocol errors such as incorrect word count/message and illegal mode codes, are not considered bus errors.

8.6.2 Source Signal. The source of data is a signal conforming to MIL-STD-1553. Format provisions are made for a dual redundant data bus system. The interface device performing the data acquisition shall be configured as a bus monitor. Figure [8-4](#) depicts in block diagram form the concept of 100 percent MIL-STD-1553 bus data acquisition.

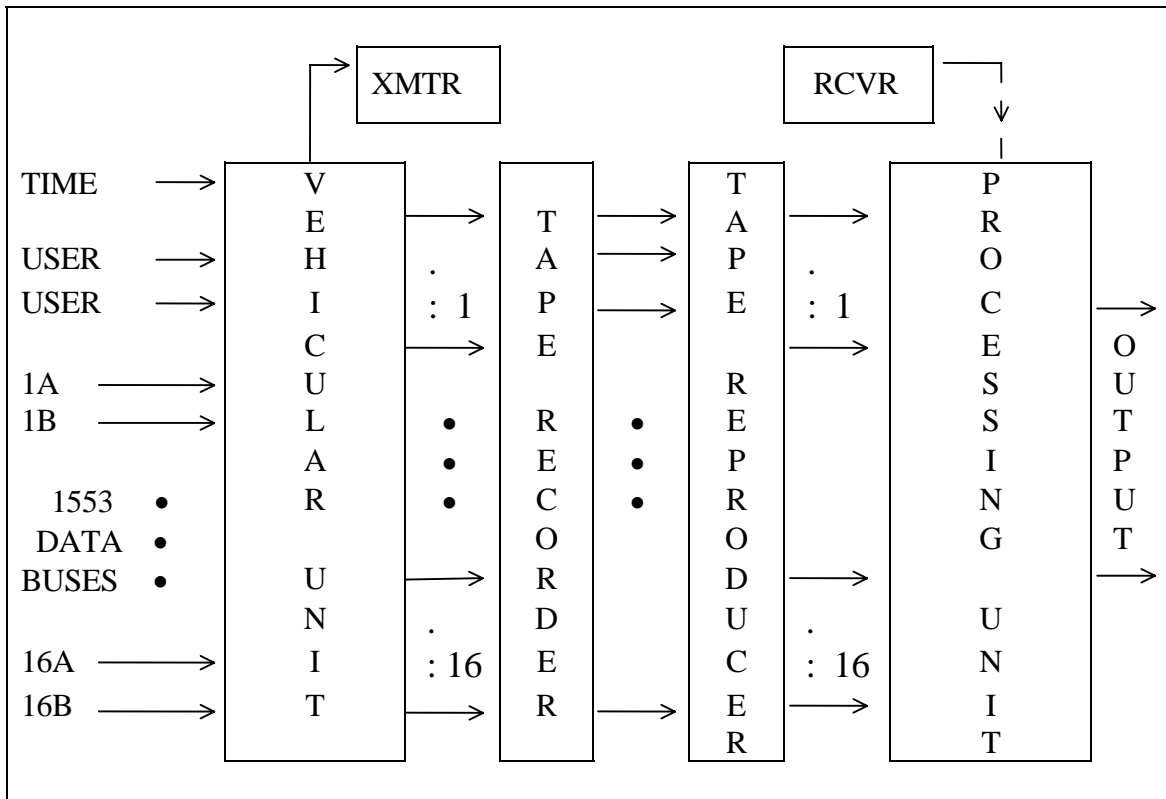

Figure 8-4. System block diagram.

 <p>NOTE</p>	<p>In the design of the interface to the MIL-STD-1553 bus, it may be necessary to include buffers to prevent loss of data and to conserve bandwidth. The buffer size is influenced by bus loading, maximum burst length, output bit rate, tape recording speed, time tagging, and auxiliary inputs.</p>
--------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

8.6.3 **Word Structure.** The specific word structure provisions to be used for MIL-STD-1553 bus formatted output are described below.

- a. The formatted data shall be a 24-bit word constructed as shown in Figure [8-1 part \(a\)](#) and Figure [8-5 part \(a\)](#).
- b. The information extracted from the MIL-STD-1553 bus shall have the synchronization pattern and parity bit removed.
- c. Each incoming MIL-STD-1553 word (Command, Status or Data), auxiliary input or time word shall be appropriately labeled with a 4-bit Content Identification Label as described in Figure [8-1, part \(c\)](#), and Figure [8-5, part \(c\)](#).
- d. Data extracted from the MIL-STD-1553 bus shall maintain bit order integrity in the information field for a command, status, data, and error word. Bit position four (4) in

the MIL-STD-1553 bus word shall be placed into bit position nine (9) in the formatted data word. The remaining bits of the MIL-STD-1553 bus word shall be placed in successive bit positions in the formatted data word. Transposing or reordering of the bits is not permitted.

- e. For bus errors as defined in paragraph [8.6.1f](#) (Error A - 1100 or Error B - 1000), the synchronization pattern and the parity bit are removed as stated in subparagraph [8.6.3.b](#). The Information Content bits, nine through 24, of the formatted word shall contain the resulting 16-bit pattern extracted from the bus.

8.6.4 Time Words.

8.6.4.1 Time Tagging. If time tagging of the occurrence of MIL-STD-1553 messages is necessary to satisfy user requirements, the first command word of the message shall be time tagged. The time words shall immediately follow the first command word in the following order: high order time, low order time, and microsecond time.

8.6.4.2 Response Time Word. The optional response time word shall have one (1) microsecond resolution and shall indicate the response time of the data bus. The response time word shall immediately precede the status word associated with it.

 <p>NOTE</p>	If the response time function is not used, Content Identification Label 0100 may be assigned to user defined inputs.
------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------

8.7 **ARINC 429**

The following subparagraphs describe specific formatting requirements for the 100 percent acquisition of ARINC 429 channel information.

8.7.1 Definitions

- a. Monitor. The receiver or sink assigned the task of receiving bus traffic and extracting all information to be used at a later time.
- b. Data Bus. All hardware including twisted shielded pair cables, required to provide a single data path between the transmitter or source and the associated receivers or sinks.
- c. Channel Error. Conditions detected which violate the definition of ARINC 429 word structure as specified in ARINC specification 429P1, 429P2, and 429P3. Conditions such as parity and bit count/word errors are all considered among word type errors. System protocol errors are not considered bus errors.

8.7.2 Source Signal. The source of data is a signal conforming to ARINC 429. Format provisions are made for up to 64 channels. The interface device performing the data acquisition shall be configured as a monitor. In principle, Figure [8-4](#) depicts in block diagram form the concept of 100 percent bus data acquisition.

8.7.3 Word Structure. The following descriptions contain specific word structure provisions to be used for the ARINC 429 formatted output.

- a. The formatted data shall be a 24-bit word constructed as shown in Figure [8-1 part \(a\)](#) and Figure [8-6 part \(a\)](#).
- b. Each incoming ARINC 429 word, auxiliary input, or time word shall be appropriately labeled with a 4-bit Content Identification Label as described in Figure [8-1 part \(c\)](#) and Figure [8-6 part \(c\)](#).
- c. The format provides for addressing of up to 64 channels. Each Bus/Group Identification Label (designated GROUP X) may be associated with up to 4 independent ARINC 429 channels through the use of a High and Low Syllable technique described in paragraph 8.7.3d below and shown in Figure [8-6](#).
- d. Data extracted from the ARINC 429 channel shall maintain bit order integrity in the Information Content field. Each ARINC 429 word is 32 bits in length. To accommodate this word length within the described format, each ARINC word is divided into two segments, each 16 bits in length. These segments will be referred to as ARINC High Syllable and ARINC Low Syllable. Figure [8-7](#) describes the mapping of the 32 bit ARINC 429 word into the Information Content bits (9 –24) of the ARINC High and Low Syllable words. Transposing or reordering of the bits is not permitted.
- e. For channel errors defined in paragraph [8.7.1c](#), the following procedure shall be followed. An error word shall be generated using the appropriate Bus/Group Identification Label and 0100 as the Content Identification Label. Bits 9-12 shall contain the Content Identification Label code associated with the appropriate ARINC High Syllable channel, bits 13 – 16 shall contain the Content Identification Label for the ARINC Low Syllable associated with that channel, and bits 17 – 24 are available for system level diagnostics and are not specified here. The next occurrence of that Bus/Group Identification Label coupled with those ARINC High and Low Syllable Content Identification Labels shall contain the respective data extracted from the channel that was deemed to be in error. The Information Content bits, nine (9) through 24, of the formatted word shall contain the resulting 16-bit pattern syllables as extracted from the channel.

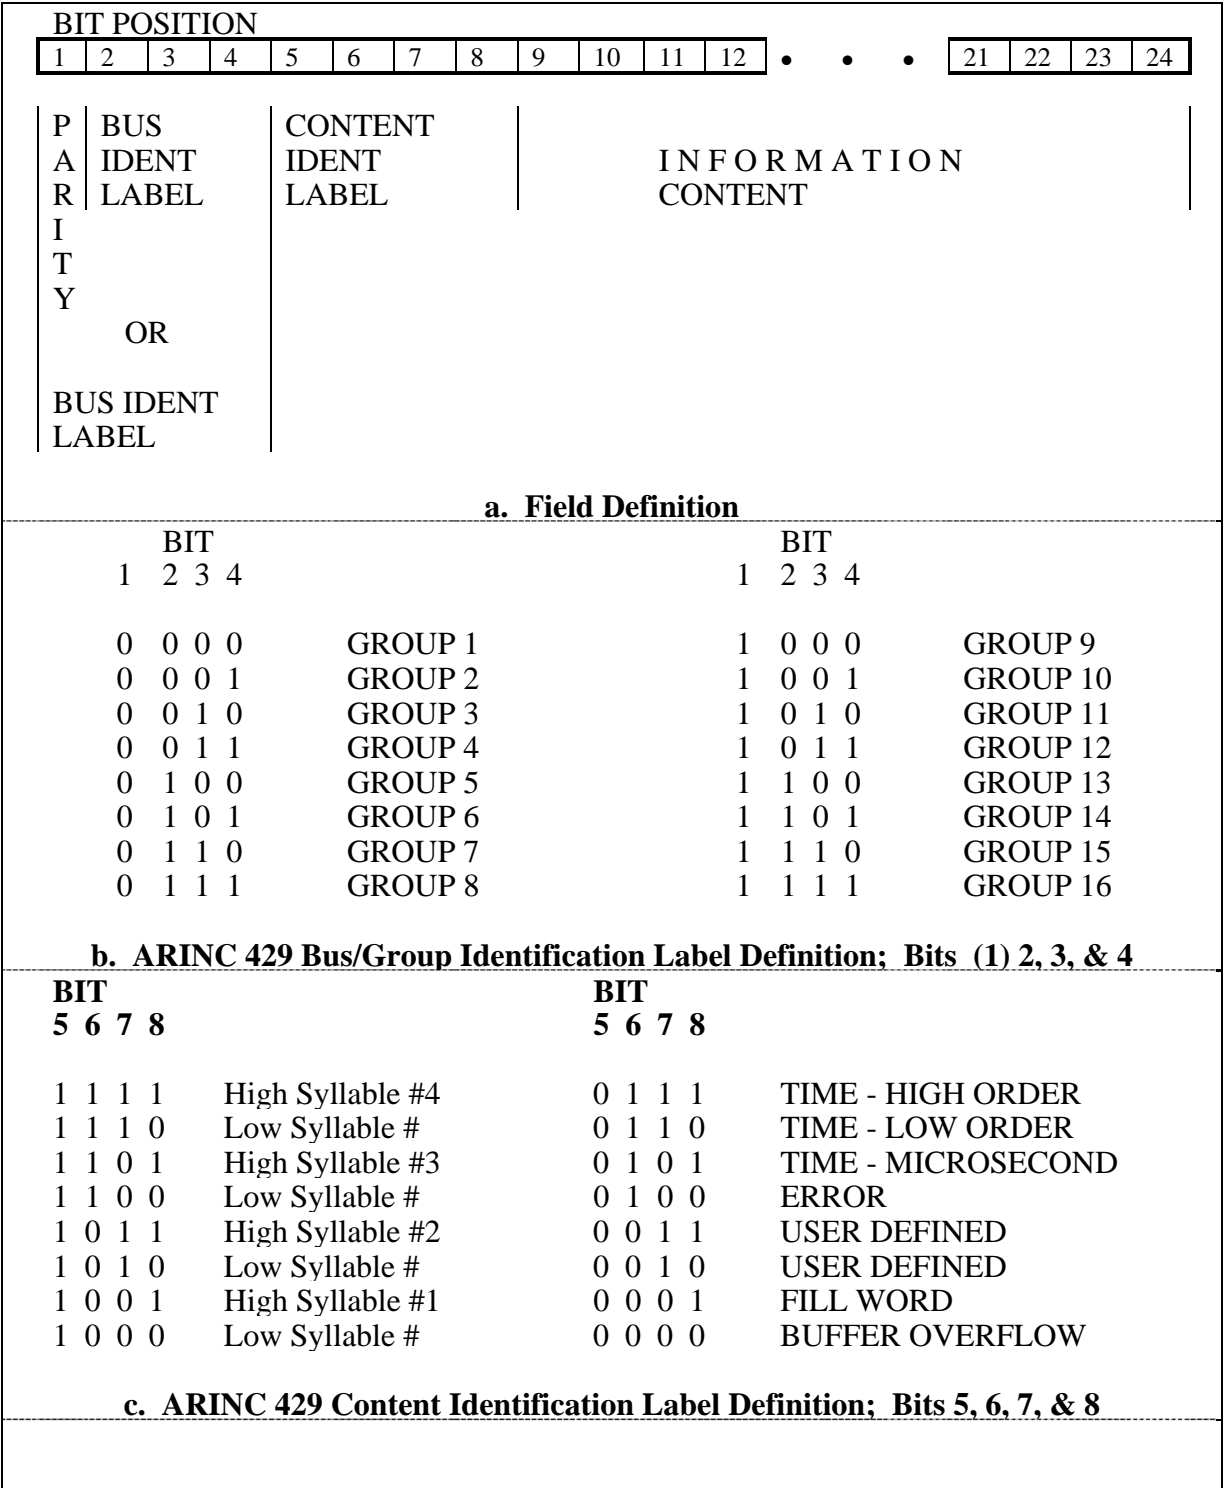

Figure 8-6. ARINC 429 formatted word construction.

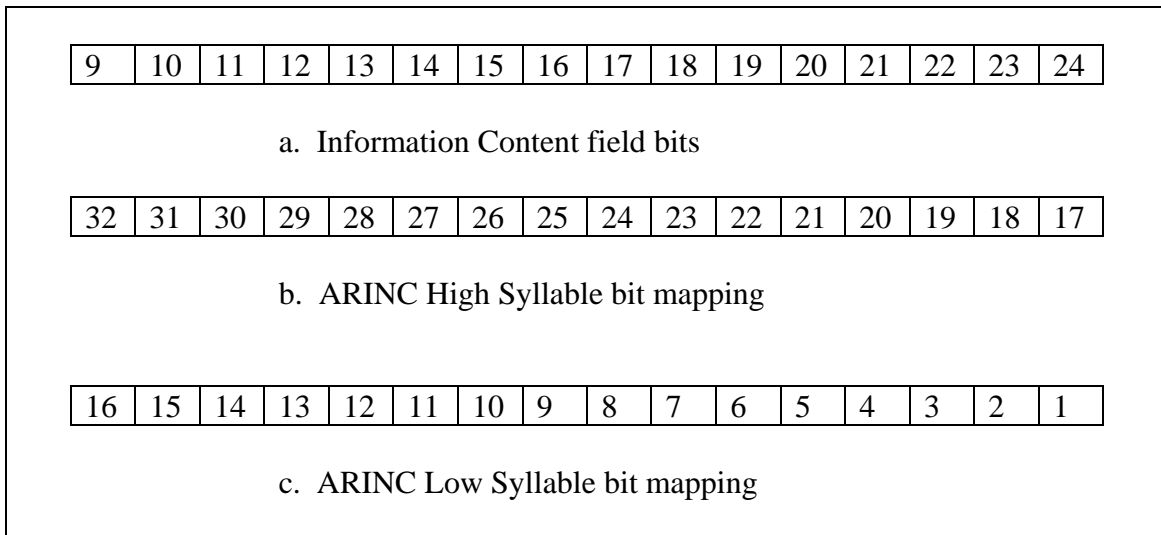

Figure 8-7. ARINC bit to formatted word bit mapping.

8.7.4 Time Words. If time tagging of the occurrence of ARINC 429 messages is necessary to satisfy user requirements, the time words shall immediately follow the ARINC Low Syllable word in the following order:

- a. High order time
- b. Low order time
- c. Microsecond time.

****** END OF CHAPTER 8 ******
